The travelling salesman problem

Definition

The travelling salesman problem (TSP) asks the following question: “Given a list of cities and the distances between each pair of cities, what is the shortest possible route that visits each city exactly once and returns to the origin city?”

Graph theory: **shortest Hamiltonian circuit**

Remember that TSP is **\mathcal{NP} -hard**!!!

History

1857 Sir W.R. Hamilton and T. Penyngton Kirkman played the Icosian Game [20 nodes]

History (cont'd)

1920 K. Menger define the TSP as known today. H. Whitney and M.

Flood promoted the problem (1930)

1954 G. Dantzig, R. Fulkerson, and S. Johnson published a description of a method for solving the TSP [49 cities]

SOLUTION OF A LARGE-SCALE TRAVELING-SALESMAN PROBLEM*

by DANIEL B. FULKERSON, and S. JOHNSON
The Ford Corporation, Dearborn, Michigan
Received August 6, 1954

* Authors: This is a report on a set of cases used in each of the 49 cities and Washington, D. C., for the nearest road distance.

THE TRAVELING-SALESMAN PROBLEM might be described as follows: Find the shortest route (tour) for a salesman starting from a given city, visiting each of a specified group of cities, and then returning to the original point of departure. More generally, given as a list a set of n cities, a set of distances, where d_{ij} represents the distance from i to j , arrange the points in a cyclic order in such a way that the sum of the d_{ij} between consecutive points is minimal. There are only a few "trivial" cases of possibilities (at most $1/2(n-1)!$) to consider, the problem is to decide a method of picking out the optimal arrangement which is reasonably efficient for fairly large values of n . Although algorithms have been devised for problems of this nature, e.g., the optimal assignment problem,** there is known about the traveling-salesman problem. We do not claim that this note shows the solution very much, what we do do is to show a way of approaching the problem that sometimes, at least, enables us to find an optimal route and prove it. In particular, it will be shown that a certain arrangement of 49 cities, one in each of the 48 states and Washington, D. C., is near, if not the nearest, road distance solution from an atlas.

* Reprinted from "The origin of the problem is somewhat obscure, it appears to have been first stated in the problem of minimum cost of networks, covering the many cities, large enough to be of any practical importance, in the mathematical literature." It may be that the solution distance tour problem was introduced by the English mathematician Thomas Kirkman in his paper on the problem of arranging the members of a school into walking parties. The latter problem is stated in the following manner: "Suppose that a schoolmaster wishes to divide a number of his scholars into walking parties in the evening, so that each party shall consist of a certain number of scholars, and that each scholar shall walk with every other scholar exactly once." This problem has been solved by the method of a certain list of 49 cities, one in each of the 48 states and Washington, D. C., is near, if not the nearest, road distance solution from an atlas.

TABLE I
Road Distances between Cities in Ascending Order

The figures in the table are distances between the two specified numbered cities, less 11, divided by 17, and rounded to the nearest integer.

The vehicle routing problem

Definition of VRP

Vehicle routing problem (VRP): “What is the optimal set of routes for a fleet of vehicles to traverse in order to deliver to a given set of customers?”
[Dantzig & Ramser 1959]

THE TRUCK DISPATCHING PROBLEM*

G. B. DANTZIG¹ AND J. H. RAMSER²

The paper is concerned with the optimum routing of a fleet of gasoline delivery trucks between a bulk terminal and a large number of service stations supplied by the terminal. The shortest routes between any two points in the system are given and a demand for one or several products is specified for a number of stations within the distribution system. It is desired to find a way to assign stations to trucks in such a manner that station demands are satisfied and total mileage covered by the fleet is a minimum. A procedure based on a linear programming formulation is given for obtaining a near optimal solution. The calculations may be readily performed by hand or by an automatic digital computing machine. No practical applications of the method have been made as yet. A number of trial problems have been calculated, however.

1. Introduction

The “Truck Dispatching Problem” formulated in this paper may be considered as a generalization of the “Traveling-Salesman Problem”. (1) In its simplest form the Traveling-Salesman Problem is concerned with the determination of the shortest route which passes through each of n given points once. Assuming that each pair of points is joined by a link, the total number of different routes through n points is $n!$. Even for small values of n the total number of routes is exceedingly large, e.g. for $n = 15$, there are 653,837,184,000 different routes. One of the authors has collaborated with Fulkerson and Johnson in developing a “cutting plane” approach for testing whether a proposed tour is optimal or finding an improved solution if it is not. (2), (3)

The Traveling-Salesman Problem may be generalized by introducing additional conditions. Thus, the salesman may be required to return to the “terminal point” whenever he has contacted m of the $n - 1$ remaining points, m being a divisor of $n - 1$. For given n and m the problem is to find loops such that all loops have a minimum point in common and total loop length is a minimum. Since the loops have one point in common, this problem may be called the “Clover Leaf Problem”. If m is small, optimal sets of m points may often be determined by inspection of a map which contains the points and the arcs connecting them. One would look for “clusters of points” and determine by trial and error the order in which they should be traversed, taking care that no loop crosses itself. However, when clusters are not present in sufficient numbers or when m is large, this procedure becomes inapplicable. In this case near-best solutions may be obtained by the algorithm in this paper.

2. The Truck Dispatching Problem

The Traveling Salesman Problem may also be generalized by imposing the condition that specified deliveries q_i be made at every point P_i (excepting the terminal point). If the capacity of the carrier

 - VRP flavours

VRP flavours

Variants

There are so many variants that it is almost impossible to enumerate them

- Capacitated VRP (CVRP)
take into account the capacity of each vehicle
- Multi Depot VRP (MDVRP)
vehicles can start and end from different depots
- Periodic VRP (PVRP)
each customer should be visited k times over the period
- Split Delivery VRP (SDVRP)
each customer can be served by different vehicles
- VRP with Backhauls
after deliveries, the trucks will collect some goods to ship back to the depot

VRP flavours (cont'd)

- VRP with Pickup and Deliveries (PDVRP)
pickup and delivery requests: a pickup must appear before a delivery
- VRP with Satellite Facilities
replenishment of a truck can occur at a satellite facility
- Open VRP (OVRP)
vehicles do not return to the depot

VRP flavours (cont'd)

- VRP with Pickup and Deliveries (PDVRP)
pickup and delivery requests: a pickup must appear before a delivery
- VRP with Satellite Facilities
replenishment of a truck can occur at a satellite facility
- Open VRP (OVRP)
vehicles do not return to the depot

Time windows

The depot is open during a **time horizon**. Each customer can be served during its **time window** (sometimes multiple time windows). There is a **service time** for each customer

A collaboration with KERPAPE

KERPAPE is a medical unit for reeducation of handicapped people in poly-traumatology

- full time patients
- patients on daily programs for several months

Transportation of handicapped persons

Medical units should organize daily the transportation of more than 75 patients:

- from home to medical center
- from medical center to home

Transportation of handicapped persons (cont'd)

- Human factor is very important
- Specialized service
- Individual needs
- Time and medical constraints

Cost of transportation

Cost is calculated from many factors

- transportation duration
- transportation distance
- number of vehicles used
- type of vehicles
- capacity of vehicles

- but most of the transportation is done by taxis. . .

Problem description

Objective

Design vehicle tours to ensure daily transportation of patients while minimizing the total transportation cost

Constraints

- vehicle capacity

Route structure

OVRP-1 & OVRP

Solution approaches

- ILP model (optimal \rightarrow 55 patients)
- ILS-TS with multiple neighborhoods

Competitive also on OVRP with Hybrid (1+1)-ES
from *Reinholz and Schneider (2013)*
and with the Tabu search heuristic (ABHC)
from *Derigs and Reuter (2009)*

110 instances from
`branchandcut.org` + Christophdes + Fisher & Jaikumar

- 104/110 best results
- D & R = 75/110, R & S = 20/110, CPU divided by 2
- Gap -0.01% from best and 0.10% from LB

Several care units

Kerpape is working with:

- the regional public hospital
- two private hospital units
- two radiography centers

Some of the patients have treatments in these units

- only in one unit
- in more than one unit
- in one of more unit and in Kerpape

Closest academic problem: Multi-depot OVRP

Contents

- 2 Transportation of handicapped people
 - Problem description
 - **Metaheuristics**
 - Results

Metaheuristics: MNS-TS

Main characteristics:

- Use of several neighborhoods (intra/inter route)
- Combined in Ejection Chains
- Solutions improved by Tabu Search
- Neighborhoods used in token-ring
- balance diversification and intensification

Neighborhoods

- based on path moves
- may use infeasible path moves
- use intra and inter route exploration

Path and path moves

Path P_i^α

- sequence of consecutive customers in the same route
- P_i^α : starts at i in route r_i and visits α customers

Path move (P_i^α, j, ω)

- remove P_i^α from one route
 - reinsert it after customer j
 - same route or not
 - path can be reverted before insertion ($\omega \in \{1, 2\}$)
-
- Contribution to length can be computed easily
 - Infeasible route can be generated (capacity, length)

Ejection chains

EC from infeasible path moves

- EC are used as a repair operator
- path moves are searched (with minimal Δ^+ length)
- are added to the EC until a feasible solution is found
- cycle detection and avoidance mechanism is used

EC from feasible path moves

- search for several moves that remain feasible
- improve the total length of the routes

List of neighborhoods

Intra route moves

Relocate

2-Opt

List of neighborhoods (cont'd)

Inter route moves

Relocate (feasible)

Path-Exchange – Cross/ICross Exchange (feasible)

2-Opt* (feasible)

List of neighborhoods (cont'd)

Inter/Intra route moves

Split route (feasible)

Ejection chains (not feasible)

Elements of the MNS-TS

In the algorithm

- \mathcal{N}_{intra} : all intra route neighborhoods
- \mathcal{N}_{inter} : all inter route neighborhoods except EC from infeasible path moves

For the Tabu Search

- \mathcal{N}_1 : EC from infeasible path move with last customer
- \mathcal{N}_2 : EC from infeasible path move with length 2
- \mathcal{N}_3 : EC from infeasible path move with length 3
- Tabu status: list of visited customers

Initial solution: Best insertion heuristic based on path moves

Metaheuristic algorithm

Algorithm 1: MNS-TS

Compute initial solution s_0 (greedy insertion)

Improve: $s \leftarrow \text{TabuSearch}(\mathcal{N}_{intra}(s_0))$

Save best: $s^* \leftarrow s$

Init: $k \leftarrow 1$

while *stopping conditions not satisfied* **do**

$s \leftarrow \text{TabuSearch}(\mathcal{N}_{inter}(s));$ Update s^*

$s \leftarrow \text{TabuSearch}(\mathcal{N}_{intra}(s));$ Update s^*

$s \leftarrow \text{TabuSearch}(\mathcal{N}_k(s));$ Update s^*

if $k = 3$ **then** $k \leftarrow 1$

else $k \leftarrow k + 1$

 Update stopping condition parameters

end

- 2 Transportation of handicapped people
 - Problem description
 - Metaheuristics
 - Results

And now, what about the real problem?

Kerpape is not really taking care of transportation

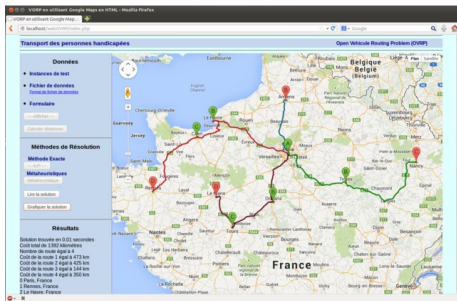

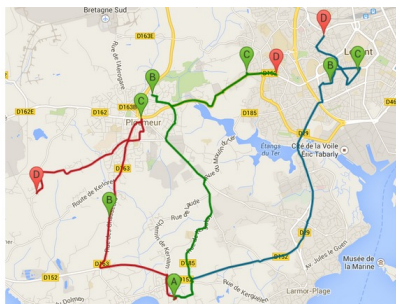

- taxis are in charge of patients
- minivans from Kerpape can be used
- → combination of open and close tours
- → distance objective is replaced by a cost objective

All transportation costs are **at the expense of social security!**

Any return for us?

Yes!!!, it was our first experience with graphical interfaces. . .

And with this, we are ready to sell our work to industry.

And how do the MNS-TS behave today?

An enormous effort has been made to update the MNS-TS code (**many thanks to Flavien!**)

Performance on the largest CVRP instances

| Instances | Init. sol. | | Final sol. | | AGS |
|------------|------------|------|------------|------|-----|
| L1 (3000) | 1.98% | 0.9m | 1.50% | 3.2m | 15m |
| L2 (4000) | 5.17% | 1.7m | 4.84% | 2.5m | 20m |
| A1 (6000) | 1.86% | 4.1m | 1.49% | 12m | 30m |
| A2 (7000) | 4.19% | 5.1m | 3.70% | 10m | 35m |
| G1 (10000) | 1.59% | 12m | 1.35% | 33m | 50m |
| G2 (11000) | 3.62% | 13m | 3.32% | 19m | 55m |
| B1 (15000) | 2.17% | 25m | 1.89% | 70m | 75m |

Conclusion: our MNS-TS is safe enough to be used for other VRP variants

Ideas where the stochastic part may come from?

Before stochastic parameters, reality is already more complicated

→ Distance graph is **non-symmetric**

Stochastic parameters are everywhere

- Travel time (more realistic than travel distance)
- Customers may raise new orders
- Customers may cancel their orders
- Quantities to deliver/collect is not precisely known

Contents

- 3 Stochastic variants of routing problems
 - Stochastic parameters
 - The stochastic CARP
 - Example of Retritex

Multiobjective Stochastic CARP = Waste collection

MOSCARP

In a network, visit a set of compulsory arcs with a fleet of capacitated vehicles, collect items along the arcs (stochastic quantities) and minimize the total travelled distance and maximum route duration (NSGA-II + LS)

Initial population

After 100 iterations

Contents

 - The stochastic CARP
 - Example of Retritex

Example of RETRITEX

A specific encounter → a general case

- general presentation at a round table
- contacted by RETRITEX a small “insertion” company

RETRITEX

- long term unemployed people
- favour manual labour
- is not a rich company

How can we collaborate?

- no data for routing
- no money for routing
- no competent people

What do they need?

One motto: **better nothing than paying**

- if they do not contribute, we cannot help them
- but the first step is often for free
- so, how do we proceed?

They have a very interesting problem

- but classical algorithms do not apply
- **with real distances**
- have too many restrictions
- want reliable solutions
- need a user interface we cannot provide easily

Why don't they just buy a routing software?

- no money, no time, lack of competences

The RETRITEX company example

Problem description

- a small fleet of heterogeneous vehicles
- containers in Brittany to collect periodically
- no idea on the containers' filling
- two intermediate storage places
- minimum and maximum capacity at depot

The RETRITEX company example

Problem description

- a small fleet of heterogeneous vehicles
- containers in Brittany to collect periodically
- no idea on the containers' filling
- two intermediate storage places
- minimum and maximum capacity at depot

Dynamic Stochastic Periodic VRP with Intermediate Facilities (+ capacity)

The RETRITEX company example

Problem description

- a small fleet of heterogeneous vehicles
- containers in Brittany to collect periodically
- no idea on the containers' filling
- two intermediate storage places
- minimum and maximum capacity at depot

Dynamic Stochastic Periodic VRP with Intermediate Facilities (+ capacity)

Today they proceed as follows:

- seasonal planning (two sets of routes)
- no prediction of containers' filling
- follow the routes whatever happens
- estimate the annual cost by reading the odometers

RETRITEX stock at the depot

RETRITEX final products

Lessons learnt from RETRITEX

Project stopped because lack of fundings ☹

But we are now convinced that we need

- a good algorithm basis ✓
- a nice interface ✗
- real distances calculation ✗
- real maps (google-like) ✗
- clickable, zoomable, with visible routes ✗

Goals

Global objectives

- Improve the urban transportation problems
- Being able to answer tomorrow's challenges
- Use massive open data available
- Combine OR and Machine Learning

Our variant of the CVRP

Objective: minimize the global cost of the routes

Several types of vehicles

- Different speeds
- Different capacities
- Restricted access zones

React depending on traffic congestion

- Collect data in real time
- Compare with prediction
 - ▶ Detect increasing traffic in used roads
 - ▶ Detect decreasing traffic on not-used roads
- Adapt dynamically the routes
 - ▶ Quick modification (short repair)
 - ▶ Neighborhood search (long repair)
- Store the experience as new data to be exploited later
- ...

Prediction from previous results

Combine machine learning and OR

- Learn
 - ▶ Instance generation
 - ▶ Resolution
 - ▶ Learning
- Create an initial solution
- Solve
- React & adapt

A new way of research

Many open questions

- How making the resolution really dynamic?
- Real data exploitation
- Which performance level?
 - ▶ Size of the instances
 - ▶ Running time
 - ▶ Reaction time (in case of event)

Operational aims

- Several types of vehicles
- Industrial expectation for performances
- Real data
- Restricted areas
- Dynamic resolution
- Simulation platform
- Need for efficient interface

A complete restart. . .

Is a new project systematically a restart from scratch?

- Not for the ideas, but
- **Yes** for the interfaces. . .

In the past years, several projects were addressed:

- School Bus Routing (Universiteit Antwerpen - BE)
- Inventory Routing (Helmut Schmidt Universität - DE)
- Robust VRP (Universiteit Antwerpen - BE)
- CARP (Université de Technologie de Troyes - FR)
- Bimodal urban transp. (Université de Valenciennes - FR)
- Clustered CVRP (Universidad de La Laguna - ES)

Clustered CVRP

Bi-objective IRP

Handicapped people transportation

How can we capitalize on previous experiences?

- We should find a way to reuse our own work
- Concentrate on what we know (OR) and let the rest
- Disconnect the interface work from the algorithm's
- Ask help of the specialists of HMI
